Locomotor Training Susan J. Harkema, Andrea L. Behrman, Hugues Barbeau, 2011 Physical rehabilitation for walking recovery after spinal cord injury is undergoing a paradigm shift Therapy historically has focused on compensation for sensorimotor deficits after SCI using wheelchairs and bracing to achieve mobility With locomotor training the aim is to promote recovery via activation of the neuromuscular system below the level of the lesion What basic scientists have shown us as the potential of the nervous system for plasticity to learn even after injury is being translated into a rehabilitation strategy by taking advantage of the intrinsic biology of the central nervous system While spinal cord injury from basic and clinical perspectives was the gateway for developing locomotor training its application has been extended to other populations with neurologic dysfunction resulting in loss of walking or walking disability

The Effect of End Effector Type Robot Training for Gait Disturbance of Brain Tumor Patients : Case Series Minji Jung, 2017

The Effect of End Effector Type Robot training for Gait Disturbance of Brain Tumor Patients Case Series

Introduction Robot assisted gait training is helpful in effectively implementing repetitive high intensity gait training. Several studies have been conducted in different areas on robot assisted gait training; however, there is little clinical research in the area of patients with brain tumor.

Purpose The purpose of this study is to investigate the effects of Morning Walk assisted gait training for patients with brain tumor.

Methods We enrolled 10 patients with brain tumor who have primary brain tumor whose functional ambulation category (FAC) scores were ≥ 2 and older than 18 years. Seven patients were dropped out because of deconditioning, recurrent brain tumor, and early discharge, leaving a cohort of 3 for final analyses. Patients were treated with 30 min of Morning Walk training with 1 h of conventional physiotherapy five times per week for 3 weeks.

Results Ten patients with primary brain tumor were enrolled. Seven patients were dropped out because of deconditioning (N=4), hydrocephalus (N=1), and early discharge (N=2), leaving a cohort of 3 patients for final analyses. After training, most outcome measures significantly improved. The outcomes with the improved score in all three patients were 10mWT, MBI, RMI, BBS, and Karnofsky performance status scale. Four out of 7 patients were discontinued due to condition deterioration and fatigue. The BFI index increased after treatment.

Conclusion After Morning Walk-assisted gait training combined with conventional physiotherapy, the level of fatigue (BFI) was deteriorated in patients with brain tumor. Four out of the seven patients who were excluded from the study stopped the therapy due to deconditioning during treatment. Therefore, if you want to apply robot therapy to brain tumor patients, you need to keep in mind the degree of fatigue and adjust the treatment time, frequency of treatment, and intensity of exercise for patients.

The use of an Alter G treadmill for gait velocity improvement in a patient with a chronic incomplete spinal cord injury Sarah Opdycke, 2017 Background and purpose Functional ambulation is considered one of the primary goals for those with incomplete spinal cord injuries SCI and can be measured using gait velocity endurance degree of independence or the need for assistive device Body weight supported treadmill training has been shown to be an effective form of treatment to improve the gait quality and velocity of those who have sustained SCIs One of these systems the Alter G anti gravity treadmill utilizes air pressure in a closed environment to create body weight support The Alter G treadmill has been used in many orthopedic populations however there are limited studies on the use in neurologic populations especially for those who have sustained SCIs The purpose of this case report was to describe the use of the Alter G treadmill and determine the efficacy of this intervention to improve gait velocity in a patient with a chronic spinal cord injury Case description The patient in this case was a 64 year old female who sustained a SCI following an automobile accident at the age of 55 years old The level of injury is C5 C6 and was classified as incomplete tetraplegia ASIA C Patient consent was obtained prior to participation in this anti gravity treadmill training intervention Pre and post gait velocity performance was measured utilizing the 10m walk test At the completion of the intervention phase the use of the treadmill training was not utilized for 6 weeks and a follow up 10m walk test was obtained Intervention Patient participated in a high intensity training program that occurred over 7 weeks with two sessions per week Each hour session included a thirty minute warm up and utilized the anti gravity treadmill for the remaining time The anti gravity treadmill training alternated high intensity walking bouts for 2 4 minute intervals with 2 minute rest breaks between intervals for a total of four sets each Intensity was adjusted over the 7 week time frame Outcomes The patient improved her intensity of use of the anti gravity treadmill for 4 sets of 3 minutes at 0 4mph to 4 sets of 3 minutes alternating 0 4mph and 0 5mph for each set over 10 sessions in 7 weeks Body weight support assistance was set at 46% and rest break length remained consistent throughout the intervention Improvements during the 10m walk test included an increase of 0 05m s from 0 09m s pre test to 0 14m s post test This was an improvement of 55% of her average velocity A six week follow up revealed a return of gait velocity to 0 09m s which was the same as baseline Discussion The anti gravity treadmill was an effective treatment to increase over ground gait velocity during a 10m walk test following a seven week intervention for a patient with a chronic spinal cord injury The patient did not meet the MCID but did meet a minimally important difference of an improvement of 0 05m s for her gait velocity The patient returned to baseline following a 6 week vacation with no therapy suggesting continued use of the treadmill training is important to maintain positive effects of the intervention

High-Intensity Exercise in Hypoxia - Beneficial Aspects and Potential Drawbacks Olivier Girard, Donald R. McCrimmon, Gregoire P. Millet, 2018-01-25 In the past traditional moderate intensity continuous training 60-75% peak heart rate was the type of physical activity most frequently recommended for both athletes and clinical populations of American College of Sports Medicine guidelines. However, growing evidence indicates that high intensity interval training 80-100% peak heart rate could actually be associated with larger cardiorespiratory fitness and metabolic function benefits and thereby physical performance gains for athletes. Similarly, recent data in obese and hypertensive individuals indicate that various mechanisms further improvement in endothelial function, reductions in sympathetic neural activity or in arterial stiffness might be involved in the larger cardiovascular protective effects associated with training at high exercise intensities. Concerning hypoxic training, similar trends have been observed from traditional prolonged altitude sojourns: Live High Train High or Live High Train Low, which result in increased hemoglobin mass and blood carrying capacity. Recent innovative Live Low Train High methods, Resistance Training in Hypoxia or Repeated Sprint Training in Hypoxia, have resulted in peripheral adaptations such as hypertrophy or delay in muscle fatigue. Other interventions inducing peripheral hypoxia, such as vascular occlusion during endurance resistance training or remote ischemic preconditioning (i.e. succession of ischemia reperfusion episodes), have been proposed as methods for improving subsequent exercise performance or altitude tolerance (e.g. reduced severity of acute mountain sickness symptoms). Postulated mechanisms behind these metabolic, neuro-humoral, hemodynamic, and systemic adaptations include stimulation of nitric oxide synthase, increase in anti-oxidant enzymes, and down-regulation of pro-inflammatory cytokines, although the amount of evidence is not yet significant enough. Improved O₂ delivery/utilization conferred by hypoxic training interventions might also be effective in preventing and treating cardiovascular diseases as well as contributing to improve exercise tolerance and health status of patients. For example, in obese subjects, combining exercise with hypoxic exposure enhances the negative energy balance, which further reduces weight and improves cardio-metabolic health. In hypertensive patients, the larger lowering of blood pressure through the endothelial nitric oxide synthase pathway and the associated compensatory vasodilation is taken to reflect the superiority of exercising in hypoxia compared to normoxia. A hypoxic stimulus in addition to exercise at high vs. moderate intensity has the potential to further ameliorate various aspects of the vascular function as observed in healthy populations. This may have clinical implications for the reduction of cardiovascular risks. Key open questions are therefore of interest for patients suffering from chronic vascular or cellular hypoxia (e.g. work-rest or ischemia reperfusion intermittent pattern, exercise intensity, hypoxic severity, and exposure duration, type of hypoxia: normobaric vs. hypobaric), health risks, magnitude, and maintenance of the benefits. Outside any potential beneficial effects of exercising in O₂-deprived environments, there may also be long-term adverse consequences of chronic intermittent severe hypoxia. Sleep apnea syndrome, for instance, leads to oxidative stress and the production of reactive oxygen species and ultimately systemic inflammation. Postulated pathophysiological changes associated with intermittent hypoxic exposure include alteration in baroreflex activity, increase in pulmonary arterial pressure, and hematocrit changes in heart structure and function, and an alteration in endothelial-dependent vasodilation in cerebral and muscular arteries. There is a need to explore the combination of exercising in hypoxia and association of hypertension, developmental defects, neuro-pathological and neuro-cognitive deficits, enhanced susceptibility to oxidative injury, and possibly increased myocardial and cerebral infarction in individuals sensitive to hypoxic stress. The aim of this Research Topic is to shed more light on the transcriptional, vascular, hemodynamic, neuro-humoral, and systemic consequences of training at high intensities under various hypoxic conditions.
